

Langflow

What is Langflow ?

Langflow is a visual programming tool built for creating LLM-powered applications. It's like a playground for builders who want to experiment with agents but don't know how to write code. With Langflow, you can connect prompts, APIs, and retrieval systems to build everything from chatbots to automated workflows, all without writing a single line of code.

Difference between Agents and Workflows:

Agents are dynamic. They make decisions and can respond to new inputs on the fly. For example, a trading agent. You fund it and ask it to make money in the market for you. It follows your rules, makes its own rules, applies trading strategies, and does everything a trader might do to maximize profits. Whether it succeeds or not depends, but at least it thrives.

Workflows, on the other hand, are static. They follow a predefined path. You give them a task, and they execute it step-by-step without mediation. For example, a YouTube scriptwriter clone. It gets a topic, searches the web, writes a script based on your guidelines, uses external APIs like 11labs for voice overs, and it follows the same path every single time.

- Agents reason and adapt.
- Workflows follow instructions
- Agents are flexible
- Workflows are predictable
